Abstract

Using a cluster-randomized controlled trial, this study evaluates the impact of group-based interpersonal therapy (IPT-G) on mental health and human capital accumulation among adolescent girls in Uganda who were at risk of moderate to severe depression at baseline. The study was designed to test whether lay provider-led IPT-G for adolescents could be effectively implemented using modest resources in a low-income country. It also tested whether a lump-sum cash transfer offered at the end of therapy provided any additional benefit. The therapy intervention alone increased the share of individuals with no depression by 5.4 percentage points (from 18.4% in the control group) 12 months after therapy, but these effects dissipated by the 30-month follow-up. Similarly, small positive effects on human capital accumulation at 12 months were not sustained at 30 months. Surprisingly, the marginal effect of offering cash transfers to IPT-G beneficiaries was large and negative on their mental health, persisting two years after baseline. The paper provides suggestive evidence that the adolescents were frustrated by their inability to use the cash toward their own goals because of the need to divert funds toward the essential needs of their families during the COVID-19 pandemic.

Keywords: adolescence, mental health, group interpersonal psychotherapy, cash transfers, COVID-19

JEL Codes: O10, C93, I15, J16, J13

2 Tables

Table 1: Mental health outcomes and category at each survey round.

Outcome	Definition	Rapid Resurvey	Midline	Endline
= 1 if Minimal Depression	PHQ-8 ≤ 4	Primary	Primary	Primary
= 1 if does not suffer from psychological distress	GHQ-12 < 3	Primary	Primary	Primary
Score on PHQ-8	Continuous score (0-24)	Secondary	Secondary	Secondary
Score on GHQ-12	Continuous score (0-12)	Secondary	Secondary	Secondary
Self-Esteem	Score on Rosenberg Self-Esteem Scale (0 – 30)	Secondary	Secondary*	Secondary
Resilience	Score on the Child and Youth Resilience Measure-Revised (0-34)	Secondary	Secondary*	Secondary
Locus of control	On a scale of 1 – 10, how much control do they feel they have over their lives	Secondary	Secondary*	Secondary

Notes: * these outcomes were not measured during the midline survey because it was implemented over the phone instead of face-to-face given restrictions due to COVID-19, and thus had to be significantly shortened.

Table 2: Human capital outcomes and category at each survey round.

Outcome	Definition	Rapid Resurvey	Midline	Endline
Desired Fertility	Desired number of children at time of survey	Primary	Secondary	Secondary
Time preferences	=1 if prefers 110,000 Uganda Shs one month from now vs. 90,000 today	Primary	Secondary	Secondary
Expectations of paid work	Probability (0-10) of engaging in paid work at age 25	Primary	Secondary	Secondary
Skill-based Competencies	Total score (0-3) on set of questions on ability to make change that test numeracy and literacy	Primary	Primary [†]	Primary
Life Expectancy	Number (0-10) of 10 young women just like respondent alive at 40	Secondary	-	-
Education Aspirations	Aspires to complete tertiary schooling*	Secondary	-	-
Desired age of first pregnancy	Wants to be pregnant within the next 5 years (1 if already pregnant)*	Secondary	-	-
Desired age of first marriage	Wants to get married within the next 5 years (1 if already married)*	Secondary	-	-
Risky Sex	=1 if no condom use at last sex	-	Primary	Primary
Incidence of marriage	Change in ever married since baseline	-	Primary	Primary
Incidence of pregnancy	Change in ever pregnant since baseline	-	Primary	Primary
School enrollment	=1 if Enrolled in School ⁺	-	Primary	Primary
Self-Efficacy	Score on Self-Efficacy Scale (10-40)	-	Primary	Primary

Notes: * Outcome is slightly different from the one that was pre-specified; + The enrolment variable is defined as enrolled in school or enrolled when school was last in session if not currently in session, or has completed secondary schooling; † the competencies score could not be measured at midline because the survey was implemented over the phone because of restrictions due to COVID-19.

Table 3: Balance at baseline.

Notes: This table shows ITT estimates of the impact of adding Cash to IPT-G on the primary and secondary human capital accumulation outcomes, comparing the IPT-G only group to IPT-G+ group; All regression models include randomization block fixed effects centered and fully interacted with treatment; Standard errors clustered at the club level in parentheses; Estimates at endline are weighted to account for the probability of selection for intensive tracking; Columns 1-6 show results for the primary outcomes: school enrolment which at midline referred to the period immediately prior to the pandemic and at endline whether they are enrolled in school if school is in session or were enrolled in school when school was last in session (or if they have completed secondary schooling), the score on the Competencies test, the score on the ? self-efficacy scale, whether they have been pregnant since baseline, whether they have married since baseline, and risky sex (whether they used a condom at their last intercourse); Columns 7-9 show results for the secondary outcomes: Time preferences (prefers 110,000 Uganda shillings in one month instead of 90,000 today), the self-reported probability of engaging in paid work at age 25, and desired fertility (desired number of children at time of survey); The rows marked as *H0:...* show the p-value for a t-test of the indicated null hypothesis on the regression coefficients and the corresponding q-values adjusting for the false discovery rate within primary and secondary outcomes and round, as per ?; Sample size differences across outcomes are due to shorter tracking questionnaires being administered to difficult-to-reach subsets of respondents.

Table 11: Impacts on adolescent’s own and perceived household response to COVID-19.

	(1)	(2)	(3)	(4)	(5)	(6)
	Adolescent’s own response				Perceived HH response	
	Get angry more quickly	Arguing more often	Talk about problems	Worry about health	Increased stress in HH	HH lost some income

Notes: This table shows ITT estimates of the impact of IPT-G and IPT-G+ on adolescents’ perceptions of their households’ and their own response to COVID-19; All regression models include randomization block fixed effects centered and fully interacted with all treatment indicators; Standard errors clustered at the club level in parentheses; Estimates at end-line are weighted to account for the probability of selection for intensive tracking; Outcomes in columns 1 to 4 are binary indicators for the adolescent respondent saying that they responded to COVID-19 by: “Getting angry more quickly”, “Arguing more often”, “Talking more often about problems with your family to find solutions”, “Fearing and worrying about your own health and the health of your loved ones”; Column 5 shows whether the respondent agrees or partially agrees that COVID-19 has increased stress in their household; Column 6 indicates whether the respondent thinks their household lost some, most, or all of their income due to COVID-19; The rows marked as *H0:...* show the p-value for a t-test of the indicated null hypothesis on the regression coefficients and the corresponding q-values adjusting for the false discovery rate within primary and secondary outcomes and round, as per ?; Sample size differences across outcomes are due to shorter tracking questionnaires being administered to difficult-to-reach subsets of adolescents.

Notes: See following page...

This table shows ITT estimates of the impact of IPT-G and IPT-G+ on the primary and secondary mental health outcomes; The treatment indicators are combined in Panel A as the Cash treatment arm was implemented after the Rapid Resurvey; All regression models include randomization block fixed effects centered and fully interacted with all treatment indicators; Standard errors clustered at the club level in parentheses; Estimates at endline are weighted to account for the probability of selection for intensive tracking; Columns 1-2 show results for the primary outcomes, indicators for whether the PHQ-8 score is ≤ 4 or the GHQ-12 score is < 3 ; Columns 3-7 show results for the secondary outcomes, the PHQ-8 and GHQ-12 raw scores, the Rosenberg Self-Esteem scale, the Child and Youth Resilience Measure-Revised, and Locus of Control, all in terms of their raw scores; The rows marked as *H0:...* show the p-value for a t-test of the indicated null hypothesis on the regression coefficients and the corresponding q-values adjusting for the false discovery rate within the primary or the secondary set of outcomes per round, as per ?; Differences in the sample size differences across outcomes are due to shorter tracking questionnaires being administered to difficult-to-reach subsets of respondents.

Notes: See following page...

Notes: This table shows ITT estimates of the impact of IPT-G and IPT-G+ on the primary and secondary mental health outcomes; The treatment indicators are combined in Panel A as the Cash treatment arm was implemented after the Rapid Resurvey; All regression models include randomization block fixed effects and baseline covariates centered and fully interacted with treatment, covariates are the poverty probability score, age, ever married, ever pregnant, and the baseline PHQ-8 score; Standard errors clustered at the club level in parentheses; Estimates at endline are weighted to account for the probability of selection for intensive tracking; Columns 1-2 show results for the primary outcomes, indicators for whether the PHQ-8 score is ≤ 4 or the GHQ-12 score is < 3 ; Columns 3-7 show results for the secondary outcomes, the PHQ-8 and GHQ-12 raw scores, the Rosenberg Self-Esteem scale, the Child and Youth Resilience Measure-Revised, and Locus of Control, all in terms of their raw scores; The rows marked as *H0:...* show the p-value for a t-test of the indicated null hypothesis on the regression coefficients and the corresponding q-values adjusting for the false discovery rate within primary and secondary outcomes (primary and secondary) and per round, as per ?; Differences in the sample size differences across outcomes are due to shorter tracking questionnaires being administered to difficult-to-reach subsets of respondents.

Table A5: Impact of therapy on mental health outcomes, LATE estimates.

	(1)	(2)	(3)	(4)	(5)	(6)	(7)

Notes: See following page...

Notes: This table shows ITT estimates of the impact of IPT-G and IPT-G+ on the primary and secondary human capital accumulation outcomes; All regression models include randomization block fixed effects and baseline covariates centered and fully interacted with treatment, covariates are the poverty probability score, age, ever married, ever pregnant, and the baseline PHQ-8 score; Standard errors clustered at the club level in parentheses; Estimates at endline are weighted to account for the probability of selection for intensive tracking; Columns 1-6 show results for the primary outcomes: school enrolment which at midline referred to the period immediately prior to the pandemic and at endline whether they are enrolled in school if school is in session or were enrolled in school when school was last in session (or if they have completed secondary schooling), the score on the Competencies test (total score (0-3) on set of questions on ability to make change that test numeracy and literacy) , the score on the ? self-efficacy scale, whether they have been pregnant since baseline, whether they have married since baseline, and risky sex (whether they used a condom at their last intercourse); Columns 7-9 show results for the secondary outcomes: Time preferences (prefers 110,000 Uganda Shillings in one month instead of 90,000 today), the self-reported probability of engaging in paid work at age 25, and desired fertility (desired number of children at time of survey); The rows marked as *H0:...* show the p-value for a t-test of the indicated null hypothesis on the regression coefficients and the corresponding q-values adjusting for the false discovery rate within primary and secondary outcomes and round, as per ?; Sample size differences across outcomes are due to shorter tracking questionnaires being administered to difficult-to-reach subsets of respondents.

Table A10: Attrition bounds, impact of adding cash to therapy on mental health.

	(1)	(2)	(3)	(4)	(5)	(6)	(7)

Notes: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$; This table shows robustness to attrition of the ITT estimates of the impact of adding cash to IPT-G to attrition on the primary mental health outcomes; Column 4 shows the baseline unadjusted estimates shown in Table 7; Columns 3 and 5 show results using the ? bounded estimator, which consists of trimming the top/bottom of the control/treatment group by the percent difference in attrition rates between the treatment and control groups (the group with the lower attrition rate is trimmed), controls include only the block fixed effects, robust standard errors in square brackets; Columns 1-2 and 6-7 show results using ? as in ?, which replace the outcomes of attriters with $\pm 0.x$ standard deviations of their respective treatment group-survey round means, lower bounds subtract this value from the treatment group and add it to the control group and vice versa for the upper bounds, controls include the block fixed effects centered and fully interacted with treatment, Standard errors clustered at the club level in parentheses.
